The Kinetics of Chemical Processes

*by Michel Boudart
Professor of Chemical Engineering
and Chemistry, Stanford University*

This text presents the kinetic analysis of elementary steps, single reactions, and reactions as an elementary level to suit the needs of the chemist interested in reactivity and the chemical engineer involved with reactors. Applications to chain and catalytic reactions and special attention to the rate equation help give the text the scope desirable for an introduction to the subject. The problems in the text are thoroughly tested, and a solutions manual is available to teachers. May 1968, 258 pp., \$7.50

Introduction to Fluid Mechanics

*Stephan Whitaker
University of California, Davis*

For use in introductory courses in fluid mechanics, this new text offers an exceptionally thorough treatment of the macroscopic (or integral) momentum and mechanical energy equations. The first half of the book is devoted primarily to theoretical analysis, leading to the differential equations of motion. Integral equations (and Bernoulli's equation) are derived and applied to a variety of practical problems, including closed and open conduit flow, compressible flow, and flow around immersed bodies. Physical and Chemical Engineering Sciences, edited by Neal Amundson. Solutions Manual to problems in the text is available upon adoption of the text. February 1968, 480 pp., \$12.00
